Reflection

In this chapter, I learned how loops are used to repeat instructions in a Java program. I learned the difference between `while` and `do-while` loops, and how counters and accumulators can be used to keep track of values and calculate totals. I also learned that infinite loops can happen when the condition is not set up correctly.

One thing I found important was learning how to debug a program. Using `println()` statements to display variable values can help me understand what is happening in my code and find mistakes more easily.

Overall, this chapter helped me understand how to make programs more efficient by using loops instead of repeating the same code many times. I still need more practice choosing the correct loop structure and checking the conditions to make sure my programs work properly.

What I Could Improve

I could improve by practising more loop problems and carefully checking how many times each loop runs. I also want to get better at finding logic errors and testing my programs with different inputs before considering them complete.
